## Late-breaking Abstracts Room Grand Ballroom A-C - Session LB1-WeA

#### **Late Breaking ALD**

Moderator: Dr. Sumit Agarwal, Colorado School of Mines

1:45pm LB1-WeA-2 Recent Advances for Spatial Atomic Layer Deposition Process: Microreactor Direct Atomic Layer Processing (µDALP™), Maksym Plakhotnyuk, A. Varga, I. Kundrata, ATLANT 3D, Denmark; J. Bachmann, FreFriedrich-Alexander Universität, Germany

In parallel to additive manufacturing leading the revolution in traditional manufacturing, the same principles can revolutionize traditional thin film deposition techniques. Where lithography and vapor phase deposition techniques struggle, for example, with rapid iterations for prototyping or incompatibility with the used chemistry, additive manufacturing can shine. Indeed, several approaches are in development for 3D nanopriting <sup>1,2,3</sup>.

Atomic Layer Deposition, and in more general Atomic Layer Processing, offers a unique opportunity for localized 3D processing/printing due to its two-step process. While simple in theory, due to well-developed examples of Spatial Atomic Layer Deposition (SALD), in practice miniturization of SALD requires substantial effort into the creation of suitable micro-nozzles. Uniquely, ATLANT 3D has developed proprietary Spatial ALD micronozzles, naming the process microreactor Direct Atomic Layer Processing -  $\mu$ DALP<sup>TM</sup>.

In recent years, the team at ATLANT 3D has been able to significantly develop the technology to reduce the μDALP<sup>TM</sup> resolution, increase material capabilities, assessable morphologies, and new instruments. Giving one example of recent development in morphologies; films deposited with  $\mu DALP^{TM}$  have conformal coverage of gratings, microchannels and trenches up to a depth of 25  $\mu m$  using a Platinum deposition process (Figure 1). Substrates with a surface roughness including Carbon nanograss (Figure 2), black silicon and anodized Aluminum Oxide membranes were also conformally coated with roughness up to an aspect ratio of 1:25 again with Platinum and TiO2. Our results demonstrate how a given ALD material process (in this case, Pt and TiO2) can be used with ATLANT 3D technology to deposit localized area conformal coatings of complex surfaces with an aspect ratio of 1:25. The µDALP™ technology enables rapid prototyping and manufacturing for an array of applications from sensors (temperature, pressure, gas sensing and capacitive) to optics, all with sensitivities that meet or exceed those of devices made using conventional vapor phase deposition techniques.4 In addition, rapid localized processing facilitated by ATLANT 3D technology of such devices enables design innovation and optimization not possible with other thin film deposition techniques and lithography.

2:00pm LB1-WeA-3 Towards Improved Conversion of Wet Waste to Jet Fuel with Atomic Layer Deposition-Coated Hydrodeoxygenation Catalysts, W. Wilson McNeary, J. Miller, S. Tacey, National Renewable Energy Laboratory; J. Travis, Forge Nano; M. Griffin, K. Jungjohann, G. Teeter, National Renewable Energy Laboratory; T. Eralp Erden, Johnson Matthey, UK; C. Farberow, National Renewable Energy Laboratory; L. Tuxworth, M. Watson, Johnson Matthey, UK; A. Dameron, Forge Nano; D. Vardon, Alder Fuels

The U.S. aviation sector has set a target for 50% reduction in  $CO_2$  emissions by 2050 (vs. 2005 levels) which will require rapid, large-scale deployment of sustainable aviation fuel (SAF). State-of-the-art SAF production relies on hydrotreating esters and fatty acids (HEFA); however, this pathway is limited by insufficient supplies of esters and fatty acids to meet future jet fuel demand, relatively high feedstock cost, and, in some cases, direct competition with food crops. Wet waste (e.g., food waste, animal manure, wastewater sludge) represents an untapped domestic resource, as most of the wet waste generated annually in the U.S., which contains more than 1.3 petajoules ( $10^{15}$  J) of energy, is either landfilled or fed to anaerobic digestors to make biogas for heat and/or electricity. To broaden the pool of renewable carbon sources available for SAF production and avoid the drawbacks of the HEFA pathway, wet waste may instead be harnessed as a SAF feedstock.

The conversion of wet waste-derived volatile fatty acids (VFAs) into jet fuelrange hydrocarbons is a promising route for increasing SAF production; Wednesday Afternoon, July 26, 2023

1

however, the cost and moderate alkane selectivity of Pt-based hydrodeoxygenation (HDO) catalysts present challenges commercialization. To address this, we used atomic layer deposition to apply TiO<sub>2</sub> overcoats to Pt/Al<sub>2</sub>O<sub>3</sub> catalysts and create new interface sites that exhibited 8 times higher site time yield of the desirable n-alkane product than uncoated catalyst. Through a combination of temperature programmed reduction, NH<sub>3</sub> temperature programmed desorption, X-ray photoelectron spectroscopy, diffuse reflectance infrared Fourier transform spectroscopy, and density functional theory calculations, we found that the increased selectivity of the ALD-coated catalyst was due to the creation of O vacancies at the Pt-TiO<sub>2</sub> interface under reducing conditions, resulting in new Ti3+ acid sites near the active metal. This ALD coating strategy was used to improve the alkane selectivity of the base 0.5 wt % Pt/Al<sub>2</sub>O<sub>3</sub> catalyst beyond that of an uncoated catalyst with an order-of-magnitude more Pt, which illustrates the benefit of utilizing the nanoscale precision of ALD to tailor interface sites and increase the atom efficiency of precious-metal catalysts.

## 2:15pm LB1-WeA-4 A Kinetic Model for Heterogeneous Nucleation in ALD and CVD, Andreas Werbrouck, S. Bent, Stanford University As atomic layer deposition (ALD) becomes an increasingly mature

technique, sound models that describe all stages of the growth are needed. Here, we develop a kinetic model for heterogeneous ALD nucleation and growth: we describe how an ALD film forms on a starting surface that is different from the steady-state growth surface, and the subsequent growth of the material after the initial surface has been covered. Understanding nucleation is relevant for any ALD process, but especially important for metal-on-dielectric deposition, where island growth is often observed, and for area-selective deposition, where nucleation on the non-growth surface to be Steady-state growth and precursor reaction kinetics are relatively wellunderstood and other models for heterogeneous nucleation have been published before. Our model, in the form of a system of differential equations, describes heterogenous nucleation kinetics in a continuous, macroscopic way as a function of time, from initial nucleus formation to coalescence and beyond. A key element of the model is the introduction of both homogeneous and heterogeneous sticking coefficients, and a description of the perimeter of the covered part of the surface. This perimeter is dependent on the ratio of the sticking coefficients. We modeled the perimeter evolution with a changing coverage for various homogeneous and heterogeneous sticking coefficients based off Monte

In the first part of the presentation, we will discuss results of our model describing heterogeneous nucleation for chemical vapor deposition. We show that the nucleation delay depends on the interplay between the homogeneous and heterogeneous sticking coefficient. In the second part, we will extend the model to a two-precursor ALD system. Due to the use of time as a parameter, the model allows us to discern between the surface change per ALD cycle and the surface change per unit time, and we report on the effect of exposure per cycle (for both precursors) on nucleation delay and growth. Thickness and coverage results can then be compared to experiment. In the final part, we will a) link the model to earlier work on catalytic surfaces b) compare the model to literature models for ALD nucleation (Avrami equation, population balance equation) and c) fit the model

Our model allows one to describe the generation of new nuclei intuitively through the heterogeneous sticking coefficient, and to explain nucleation enhancement, delay, and breakthrough behavior, while avoiding assumptions on (hemi-)spherical particles. In future work, we will expand our model to incorporate surface diffusion and substrate geometry.

# 2:30pm LB1-WeA-5 Intrinsic Area Selective Atomic Layer Deposition of MoS<sub>2</sub> Thin Films, J. Soares, Wesley Jen, Boise State University; J. Wensel, Micron Technology; S. Hues, E. Graugnard, Boise State University

As the critical dimensions in today's semiconductor devices continue to shrink, new methods for device fabrication are paramount for continued reduction in scaling. These fabrication processes must be adaptable in order to evolve with future technology nodes and scales, while providing flexible material integration techniques within the high complexity of device structures. Area selective atomic layer deposition (ASALD) is a deposition technique that utilizes a bottom-up patterning approach for self-alignment of deposited materials. ASALD operates on the basis that functional groups either present or absent on a growth surface will promote or inhibit nucleation. This contrast can lead to selective deposition. In addition to compatible processing techniques, next

generation materials also need to be studied. Layered two-dimensional (2D) molybdenum disulfide (MoS<sub>2</sub>) is a semiconducting material that shows great promise due to its atomically thin structure and impressive electrical properties. In this work, we report the ASALD of MoS<sub>2</sub> on patterned template substrates of common dielectric materials versus thermal silicon oxide and nitride. Growth and non-growth surfaces were initially screened with X-ray photoelectron spectroscopy (XPS) characterization of blanket MoS<sub>2</sub> films after numerous ALD cycles. The selectivity parameter between surfaces was calculated using XPS, revealing a high selectivity of S = 0.94 after 20 ALD cycles for growth on ALD alumina versus thermal silicon oxide. These results identified contrasting surfaces that were then patterned to investigate area selectivity. MoS<sub>2</sub> ALD was performed at 200 °C on patterned surfaces that were then annealed at 650 °C for 30 minutes. Samples were characterized using Raman spectroscopy maps of crystalline MoS<sub>2</sub> modes and time-of-flight-secondary ion mass spectroscopy (ToF-SIMS) elemental mapping, which confirmed ASALD. These results hold promise for advancing the integration of 2D materials into device manufacturing.

2:45pm LB1-WeA-6 Selective Deposition of HfO2 on Aminosilane-treated TiN/SiO2 Substrates, Yujin Lee, Stanford University; H. Kim, Samsung Advanced Institute of Technology, Republic of Korea; S. Bent, Stanford University

For the continued downscaling of semiconductor devices, new approaches are required to meet the fabrication challenges. Area-selective atomic layer deposition (AS-ALD) is a bottom-up fabrication process that provides a great opportunity to overcome the problems associated with current top-down fabrication processes such as cost and complexity. Toward the implementation of an AS-ALD process at the sub-10 nm level, studies on AS-ALD using small molecule inhibitors (SMIs) having angstrom level thickness have been reported. However, since SMIs contain carbon species, their use in an inhibitor layer could affect the device's characteristics such as dielectric constant and leakage current density. On the other hand, various techniques of readily-available surface treatments can be utilized to functionalize the surfaces so that they are deactivated for reducing nucleation without adding carbon species.

In this study, we develop a surface treatment process that uses an aminosilane molecule to block the adsorption of Hf precursors for HfO<sub>2</sub> ALD. We show that SiO<sub>2</sub> surfaces functionalized by the aminosilanes add only terminal -SiH<sub>3</sub> to the surface without attaching carbon species. In addition, because both standard ALD and AS-ALD processes are strongly dependent on the precursor, tuning the ALD precursor provides another variable by which selectivity may be achieved. We first investigate the effect of ALD precursor on the growth characteristics and film properties for three different Hf precursors with alkylamide, alkoxide, and halide ligands, respectively. Using these three different optimized HfO2 ALD processes and adding surface functionalization steps, we perform AS-ALD on TiN/SiO<sub>2</sub> substrates. ALD blocking results show that the resulting hydride (-SiH<sub>3</sub>)functionalized SiO2 surface can successfully inhibit the adsorption of the Hf precursor without the need for carbon species at the surface. Best results were found using the Hf alkoxide precursor, for which selectivities of greater than 80% were achieved after 30 cycles of HfO2 ALD. This work introduces a new surface treatment together with considerations for ALD precursor selection to enable an AS-ALD process.

3:00pm LB1-WeA-7 Atomic Layer Deposited Zr-doped HfO<sub>2</sub> (HZO) and Indium Gallium Oxide (IGO) Thin Films for 3D Gate-All-Around FeFET, Boncheol Ku, J. Hur, J. Jeong, C. Choi, Hanyang University, Korea

Recently, HfO<sub>2</sub>-based ferroelectric (FE) field effect transistors (FeFETs) have gained attention for NAND flash memory applications due to their superior advantages compared to  $SiO_2/Si_3N_4/SiO_2$  (ONO)-based FETs. These advantages include faster write/erase speeds, non-destructive readout, lower operation voltage, higher scalability, and CMOS compatibility. However, when FE thin films are applied to poly-Si, there can be issues such as grain-dependent threshold voltage ( $V_{th}$ ) degradation and temperature-induced  $V_{th}$  instability due to the low-k interfacial layer formed at the interface between FE-HfO<sub>2</sub> and poly-Si. With this regard, materials system using suitable FE thin film and oxide semiconductor should be explored and corresponding device feasibility needs to be investigated. To address this, we have proposed using atomic layer deposited (ALD) FE thin film and oxide semiconductors (OS) as charge trapping layer and alternative channel, respectively, in 3D NAND architecture.

In this study, we successfully demonstrated ALD Zr-doped  $HfO_2$  (HZO) FE thin film and an indium-gallium oxide (IGO) channel for a 3D vertical Gate-All-Around (GAA) NAND flash memory device using with gate length ( $L_g$ )

and spacer length (L<sub>s</sub>) of 50 nm. [Fig. 1] These FE and OS thin films are adopted as an alternative charge trapping layer and channel layer alternative ONO and poly-Si, respectively. The  $l_d\text{-}V_g$  characteristic of the 3D GAA FeFET device indicates high-quality interface between the HZO and IGO thin films, with subthreshold swing of 90 mV/dec and almost no hysteresis under bias sweeping. The device shows a maximum memory window (MW) of 2.5 V, allowing for potential multilevel cell (MLC) operation. The stable sub-loop switching of ferroelectricity for MLC memory operation is an important factor, and stable 2 bits/cell retention properties up to  $10^4\,\text{sec}$  at room temperature are achieved, extrapolated to 10 years retention time. [Fig. 2]. These results suggest that ALD FE thin film and OS materials can be a promising alternative to current ONO/poly-Si materials for advanced V-NAND flash memory applications.

3:15pm LB1-WeA-8 Development of Robust Gate Insulators for MIS-HEMT Structures Based on ALD/PEALD Techniques, Messaoud Bedjaoui, S. Cadot, J. Amiran, R. Contie, A. Thiam, C. Bout, CEA/LETI-University Grenoble Alpes, France; P. Fernandes Paes Pinto Rocha, CEA/LETI-University Grenoble Alpes, Grenoble INP-LTM, France

In the past few years, AlGaN/GaN based metal-insulator-semiconductor high-electron-mobility transistors (MIS-HEMTs) have attracted considerable interest, providing unprecedented power levels and efficiencies. The dielectric quality as well as the GaN-dielectric interface play a critical role in the performances of such devices. Atomic Layer Deposition (ALD) and Plasma Enhanced-ALD are the most suitable techniques to address the challenge of MIS gate dielectrics. As such, the Al $_2$ O $_3$  layers grown by ALD are materials of choice due to high dielectric constant, high breakdown field and high conduction-band offset on GaN. However, the dielectric performances of Al $_2$ O $_3$  rapidly degrade at high temperature (above 800°C) due to the crystallization. One promising strategy for high quality gate dielectrics consists in combining SiO $_2$  and Al $_2$ O $_3$  deposits in order to prevent the dielectric crystallization.

In this work, we analyse the general performance of MIS gate dielectrics (with and without post deposition annealing or PDA) using physicochemical (X-ray photoelectron spectroscopy, X-ray reflectometry, grazing incidence X-ray diffraction) and electrical analyses (Hg probe measurements, MOSCAPs). We primarily focused on the evaluation  $Al_2O_3/SiO_2$ -based films (thickness range 20-30nm) obtained by two thermal ALD modes (300°C) on silicon substrates: (i) alternating the deposition of separate  $SiO_2$  and  $Al_2O_3$  layers (nanolaminate); (ii) combination of ALD super cycles allowing the formation of  $AlSiO_8$  layers.

For the ALD super cycles approach (50% SiO2 content according to XPS analysis), XRR density and permittivity values of AlSiO<sub>x</sub> layers are around 2.8 and 5, respectively. We outline the close correlation between the Al/Si ALD process ratio and the AlSiO<sub>x</sub> composition. AlSiO<sub>x</sub> layers preserve their density and permittivity values after PDA treatment unlike Al2O3 layers (using H<sub>2</sub>O or O<sub>3</sub> oxidant, see Fig. 1 and 2). This is attributable to the fact that AlSiO<sub>x</sub> stays amorphous up to 850°C, as revealed by GIXRD analyses (see Fig. 3). We report a drastic decrease of leakage current and an increase of breakdown field in comparison to Al<sub>2</sub>O<sub>3</sub> layers before and after PDA treatment at 850°C (see Fig.4). This trend prevails for both ALD multilayer and ALD super-cycles approaches confirming the deep impact of SiO<sub>2</sub> fraction in the AlSiOx layers composition and subsequently on the general electrical performances. Furthermore, preliminary evaluation of interface passivation layers (such as in-situ plasma clean or PEALD-deposited AIN barrier) underlines the great potential of ALD/PEALD techniques in the fabrication of robust gate insulators for AlGaN/GaN-based HEMTs.
